Sequence

- When the operation of the equipment can be divided into clear steps, it is also worth dividing the program into steps or sequences → Not difficult block hassle in a single program circuit/network. If program is more complex divide the program into small entities into several networks or even separate functions (FC/FB).
- Each step implements one function, for example::
 - Cylinder movement out or in
 - Filling the tank with a pump up to the upper limit
 - Stir material in the tank
- The steps have their own memory bits, based on which the program knows which step is active.
- When a step is completed – the transfer condition is fulfilled – program move in to the next step, which initially resets the step memory bit of the previous step and then performs the actions that are part of the step
- Drilling jig (Exercise 2 and 3) and trolley track exercises are typical examples of sequence programming. In these, the functions can be easily divided into separate steps.

Example
